

# Version Control & Basic Unix Commands

# What is GitHub and why do we use it?

- ✦ “code hosting platform for version control and collaboration”
- ✦ Version control keeps track of your changes and why you made them
- ✦ Keeps your code in one place (easy to keep updated when working on multiple computers)
- ✦ Allows you to easily collaborate and share your work with others for feedback

## Installing GitHub

- ✦ <https://github.com/> <sup>\*\*</sup>(where most text from this tutorial is taken)
- ✦ <https://desktop.github.com/>

# Important Terms

- ✦ **Git**- version control GitHub is built on top of
- ✦ **GitHub**- company name of the software that help you interact with Git repositories
- ✦ **GitHub.com**- website that you log into to view repositories online
- ✦ **GitHub Desktop**- application that helps you synchronize the local code on your computer with GitHub.com

# Important Terms

- ✦ **repository**- contain folders and files, images, videos, spreadsheets, and data sets and is used to organize a single project
  - ✦ We will have a “Kalan Lab” Repository for general lab scripts. The test repository today is for practice.
  - ✦ Can be **private** (only you or your collaborators can see code in it, but requires academic or paid subscription) or **public** (anyone can see it but you choose who is allowed to make changes to it)
- ✦ Stored in two places
  - ✦ locally on your computer- you can work on it without internet connection
  - ✦ remotely on [GitHub.com](https://github.com)

# Important Terms

- ✦ **commit**- a saved change that is associated with a **commit message** denoting why the change was made
- ✦ once commit changes to your local repository, you want to **push** these changes to the remote repository
- ✦ before you start working, you will want to **pull** changes that have been made to make sure you are working with the most up to date copy
- ✦ if you made a bad change and want to go back, you can **revert** a commit

# Important Terms

- ✦ **branching**- a way to work on more than one version of a repository at a time
  - ✦ \*Generally we are all working on the main branch
- ✦ **pull request**- proposing changes and requesting that someone review and pull in your contribution and merge them into their branch

# Important Terms

- ✦ **Cloning** a repository creates a new local copy of a repository on your computer
- ✦ A **fork** is also a copy of a repository. Forking a repository allows you to freely experiment with changes without affecting the original project

# Kalan Lab Repository

- ✦ **bin**- basic lab scripts for things like running QIIME, calculating fasta or fastq read lengths, etc.
- ✦ **mapping\_files**
  - ✦ FreezerTracking
  - ✦ metadata- sample information associated with studies
  - ✦ run\_maps- sequencing run information
- ✦ **reference**
- ✦ **scripts**- contains folder for each lab member to store project specific scripts

# Basic Unix Commands

- ✦ **man *command*** - gives you the manual with information on what the command does and different flags you can use
- ✦ **echo** - write arguments to standard output
- ✦ **ls** - lists your files
- ✦ **ls -hl** - lists your files in human readable long format
- ✦ **ls -a** - lists all files
- ✦ **du -h** tells you disk usage

# Basic Unix Commands

- ✧ **pwd** - print working directory (i.e. tells you where you are)
- ✧ **mkdir *dirname*** - makes a new directory
- ✧ **cd *dirname*** - change directory
- ✧ **rmdir *dirname*** - removes a new directory \*\* be very careful- this permanently deletes files (rather than sending to trash can)

# Basic Unix Commands

- ✧ ***mv filename1 filename2*** - moves a file (i.e. renames a file or moves it to a different directory)
- ✧ ***cp filename1 filename2*** - copies a file
- ✧ ***rm filename*** - removes a file \*\* be very careful- this permanently deletes files (rather than sending to trash can)
- ✧ adding a ***-r*** flag to each command means to apply the commands recursively (i.e. to the listed directory and all contents within the directory)

# Commonly used text editors

- ✧ **emacs**

- ✧ **vim**

- ✧ **nano**

- ✧ `nano filename.txt`

- ✧ `control+o` = write file

- ✧ `control+x` = exit

# Using GitHub

- ✦ Make a new temporary file under the scripts folder in your username directory
- ✦ Commit this change
- ✦ Alternatively, you can use the GUI...

```
cd ~/Kalan_lab/scripts/Ikalan/
```

```
git pull
```

```
git status*
```

```
mkdir test
```

```
cd test
```

```
nano test.txt
```

```
git add test.txt
```

```
git commit -m "adding a test file"
```

```
git status*
```

```
git push
```

\*optional

# Other Fun Unix Commands

- ✦ **wc filename** - tells you how many lines, words, and characters are in a file
  - ✦ if working with a single-line fasta file, where the first line is the header and the second line is the sequence, you can use **wc -l** to count the number of lines in the file and divide it by 2 to get your sequence count (for fastq files, you divide by 4)
- ✦ **grep string filename(s)** - searches for a string within a file
  - ✦ if working with fasta file, grep for the header carrot ">" and use the -c flag to count the number of sequences in your file

# Other Fun Unix Commands

- ✧ **chmod *options filename*** - lets you change the read, write, and execute permissions of a file
  - ✧ ex. `chmod u=rwx,g=rx,o=r myfile.txt`
- ✧ **whoami** - returns your username

# Executing scripts

- ✧ A script is a list of commands in a single file
- ✧ The first line in the script contains the “shebang” (`#!`) that tells the system which interpreter to use
  - ✧ So, for a bash script, the shebang would be `#!/bin/sh`, whereas if you wrote the script in perl, it would be `#!/bin/perl`
- ✧ Let’s write and execute a test bash script...

# Copying files

- ✦ **scp** (secure copy)
- ✦ **scp *source destination***

Alternative: use FileZilla (<https://filezilla-project.org/>)
